What is a radionuclide cystogram?

A radionuclide cystogram is a test that uses a small amount of radioactive material to help doctors see the inside of the bladder and ureters. The radioactive material is injected into the bladder through a catheter. The doctor will then take pictures of the bladder and ureters to see if there are any problems.

How is a radionuclide cystogram done?

The test is done in a hospital or clinic. The doctor will first clean the area around the bladder. Then, the doctor will insert a catheter into the bladder. The radioactive material will be injected into the bladder through the catheter.

The doctor will then take pictures of the bladder and ureters. The pictures will show the shape and size of the bladder and ureters. The doctor will also look for any blockages or other problems. The test usually takes about 30 minutes to complete. The radioactive material will be excreted from the body through the urine.

The doctor will explain the results of the test to you. The doctor will also explain what to do if you have any questions about the results. The doctor will also explain how to care for your child after the test.

If you have any questions about the test, please call your doctor. Your doctor will be happy to help you.

Does my child have to do anything different before the test?

1. Your child will need to fast for 4 hours before the test. This means that your child cannot eat or drink anything for 4 hours before the test. This includes water, juice, and milk.

What else should I know about coming for the test?
